

Ex.No.1	USES OF CONTROL STATEMENTS IN PYTHON	Reg.No: URK23CS1261
13.12.23		

### 1 A). Write a program to find the factorial of a number using while loop.

**Aim:** The objective of this program is to find the factorial of a number using while loop.

#### Algorithm:

- Step 1: Start the program.
- Step 2: Declare a variable 'num' for storing input from user.
- Step 3: Define a function called 'factorial' with parameter 'num'.
- Step 4: Declare variables 'fact' and assign value as 1 then another variable 'i' for iteration.
- Step 5: Use a while loop to calculate factorial.
- Step 6: Return the factorial value.
- Step 7: Calculate factorial using the function.
- Step 8: Print the factorial.
- Step 9: Stop.

#### Program:

```
def factorial(num):
```

```
    fact = 1
```

```
    i = num-1
```

```
    while i > 0:
```

```
        fact *= num-i+1
```

```
        i-=1
```

```
    return fact
```

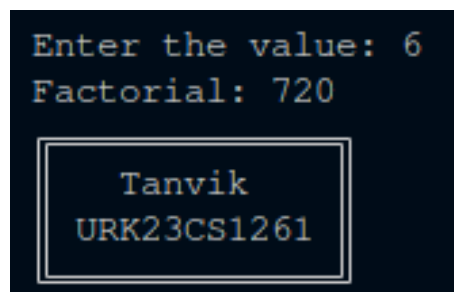

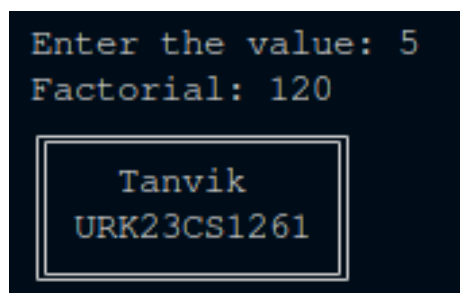

```
num = int(input("Enter the value: "))
```

```
fact = factorial(num)
```

```
print(f'Factorial: {fact}')
```

```
print("=====\\n|| Tanvik ||\\n|| URK23CS1261 ||\\n=====")
```

#### Output:

**Result:** Thus, The program has successfully produced the desired output.

**1 B) Write a Python program to check whether a number is Prime or not.**

**Aim:** The objective of this program is to find the given number is whether prime or not.

### Algorithm:

Step 1: Start the program.

Step 2: Declare a variable 'num' for storing input from user.

Step 3: Check if the number is prime or not.

Step 4: If the number satisfies the conditions, print that it is a prime number.

Step 5: If the number doesn't meet the conditions, print that it is not a prime number.

**Step 6: Stop.**

**Program:**

```
num = int(input("Enter the number: "))
```

```
if((num % 2) != 0 or num == 2):
```

```
print(f"Given number('{num}') is Prime")
```

else :

```
print(f'Given number(' {num}') is not Prime')
```

```
print("_____\\n Tanvik \\n URK23CS1261 \\n_____")
```

### Output:

```
Enter the number: 13
Given number('13') is Prime
```

Tanvik  
URK23CS1261

```
Enter the number: 12
Given number('12') is not Prime
```

Tanvik  
URK23CS1261

**Result:** Thus, The program has successfully produced the desired output.

**1 C) Write a Python program to print alphabet pattern 'E'.**

\* \* \* \* \*  
 \*  
 \*  
 \* \* \* \* \*  
 \*  
 \*  
 \* \* \* \* \*

**Aim:** The objective of this program is to print alphabet pattern 'E'.

### Algorithm:

Step 1: Start the program.

Step 2: Use for to loop 'i' for 5 times using range.

Step 3: Check if the 'i' is equal to 0 or 4 or 2.

Step 4: If the number satisfies the conditions, print '\*' five times.

Step 5: If the number doesn't meet the conditions, print '\*' one time.

Step 6: Stop.

**Program:**

```
for i in range(5):
    if i == 0 or i == 4 or i == 2:
        print("*" * 5)
    else:
        print("")
```

```
print(" _____\n|| Tanvik ||\n|| URK23CS1261 ||\n|| _____")
```

### Output:

**Result:** Thus, The program has successfully produced the desired output.

**1 D) Write a Python program that iterates the integers from 1 to 15. For multiples of two print "Karunya" instead of the number and for the multiples of three print "University". For numbers which are multiples of both two and three print "KarunyaUniversity".**

**Aim:** The objective of this program is to iterate through integers from 1 to 15. For multiples of two, it will print 'Karunya' instead of the number, and for multiples of three, it will print 'University'. If a number is a multiple of both two and three, it will print 'KarunyaUniversity'."

**Algorithm:**

Step 1: Start the program.

Step 2: Declare a variable 'num' for storing input from user.(15)

Step 3: Declare two strings 'str1' as "Karunya" and 'str2' as "University".

Step 4: Iterate through the range from 1 to 'num'.

Step 5: For each number in the range:

- a. Check if the number is a multiple of both 2 and 3.
  - i. If true, print the concatenation of 'str1' and 'str2'.
- b. Check if the number is a multiple of 2.
  - i. If true, print 'str1'.
- c. Check if the number is a multiple of 3.
  - i. If true, print 'str2'.

Step 6: Stop.

**Program:**

```
num = int(input("Enter the number: ")) #15
```

```
str1 = "Karunya"
```

```
str2 = "University"
```

```
for x in range(1,num+1):
```

```
    if(x % 2 == 0 and x % 3 == 0):
```

```
        print(str1+str2)
```

```
    elif(x % 2 == 0):
```

```
        print(str1)
```

```
    elif(x % 3 == 0):
```

```
        print(str2)
```

```
print("===== \n || Tanvik || \n || URK23CS1261 || \n =====")
```

**Output:**

```
Enter the number: 15
Karunya
University
Karunya
KarunyaUniversity
Karunya
University
Karunya
KarunyaUniversity
Karunya
University

Tanvik
URK23CS1261
```

**Result:** Thus, The program has successfully produced the desired output.

### 1 E) Write a python program to check whether the number is palindrome or not.

**Aim:** The objective of this program is to check whether the number is palindrome or not.

#### Algorithm:

Step 1: Start the program.

Step 2: Declare a variable 'num' for storing input from user.

Step 3: Initialize variables 'pal' and 'i' with 'num'.

Step 4: Use a 'while' loop to reverse the number 'num' and store it in 'pal'.

Step 5: Check if the reversed number 'pal' is equal to the original number 'num'.

a. If they are equal, print that it is a palindrome number.

b. If they are not equal, print that it is not a palindrome number.

Step 6: End the program.

Step 6: Stop.

#### Program:

```
num = int(input("Enter the number: "))
```

```
pal, i = 0, num
```

```
while i > 0:
```

```
    pal = pal* 10 + (i % 10)
```

```
    i //= 10
```

```
if(pal == num):
```

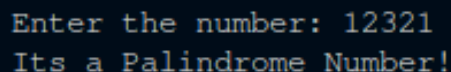

```
    print("Its a Palindrome Number!")
```

```
else:
```

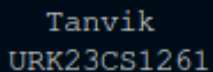

```
    print("Its not a Palindrome Number!")
```

```
print("=====\\n|| Tanvik ||\\n|| URK23CS1261 ||\\n=====")
```

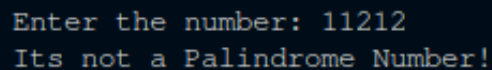

#### Output:

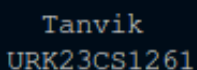

```
Enter the number: 12321
Its a Palindrome Number!
```

```
Tanvik
URK23CS1261
```

```
Enter the number: 11212
Its not a Palindrome Number!
```

```
Tanvik
URK23CS1261
```

**Result:** Thus, The program has successfully produced the desired output.

### 1 F) Write a python program to check whether the number is Armstrong number or not.

**Aim:** The objective of this program is to check whether the number is Armstrong number or not.

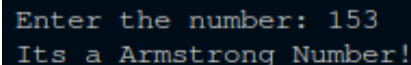

#### Algorithm:

- Step 1: Start the program.
- Step 2: Declare a variable num for storing input from user.
- Step 3: Initialize variables 'arm' and 'i' with 'num'.
- Step 4: Use a 'while' loop to calculate the Armstrong number.
  - a. Extract the last digit of 'i' and add its cube to 'arm'.
  - b. Update 'i' by removing its last digit.
- Step 5: Check if the calculated 'arm' is equal to the original number 'num'.
  - a. If they are equal, print that it is an Armstrong number.
  - b. If they are not equal, print that it is not an Armstrong number.
- Step 6: Stop.

#### Program:

```
num = int(input("Enter the number: "))
arm, i= 0, num
while i > 0:
    arm += (i % 10) ** 3
    i //= 10
if(arm== num):
    print("Its a Armstrong Number!")
else:
    print("Its not a Armstrong Number!")
print("┌───────────────────┐\n┆ Tanvik ┆\n┆ URK23CS1261 ┆\n└───────────────────┘")
```

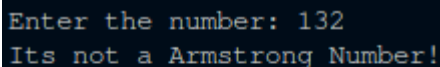

#### Output:

```
Enter the number: 153
Its a Armstrong Number!
```

```
Tanvik
URK23CS1261
```

```
Enter the number: 132
Its not a Armstrong Number!
```

```
Tanvik
URK23CS1261
```

**Result:** Thus, The program has successfully produced the desired output.
